## System

- 4-wave mixing as per Vogels et a/[1] experiment (but less atoms).
- Initial Na BEC formed in cigar-shaped $20 \times 80 \times 80 \mathrm{~Hz}$ trap.
- Trap turned off at $\mathrm{t}=0$.
- Collision along the axial direction "x".

| original condensate | $2 \%$ seed wave produced by second Bragg pulse |
| :---: | :---: |
|  | $\because$ second condensate produced by Bragg optical transition |
|  | an $\approx$ spherical shell correlations calculated from here $v_{y}=v_{Q}$ |
|  | miltonian density: |
| $\widehat{H}=\frac{\hbar^{2}}{2 m} \nabla \widehat{\Psi}^{\dagger} \nabla \widehat{\Psi}+V(x) \widehat{\Psi}^{\dagger} \widehat{\Psi}+\frac{g}{2} \widehat{\Psi}^{\dagger 2} \widehat{\Psi}^{2}$ |  |

Boson creation operators $\widehat{\Psi}^{\dagger}(x)$ at $x$.

## Method

## positive P representation

$\hat{\rho}=\int P(\vec{v}) \bigotimes_{x}|\alpha(x)\rangle\left\langle\beta^{*}(x)\right| d \vec{v}$

- Probability distribution $P$ of variables $\vec{v}=\{\vec{\alpha}(\vec{x}), \vec{\beta}(\vec{x})\}$ which specify LOCAL coherent state projectors.
- 2 complex variables per lattice point.
- Describes any quantum state.
- Correspondences:

1. Master equation for $\hat{\rho}$.
2. $\rightarrow$ Fokker-Planck equation for $P$.
3. $\longrightarrow$ Stochastic equations for $\vec{\alpha}, \vec{\beta}$

- Quantum observables correspond to appropriate averages of variables $\vec{v}$

$$
\widehat{\Psi}(x) \leftrightarrow \alpha(x) \quad \widehat{\Psi}^{\dagger}(x) \leftrightarrow \beta(x)
$$

## Dynamics

Just Gross-Pitaevskii equations plus Gaussian noise

$$
\begin{aligned}
\frac{d \alpha(x)}{d t}= & -i \hbar \sum_{y} \omega_{x y} \alpha(y)-\frac{i g}{\Delta x} \alpha(x)^{2} \beta(x) \\
& +i \sqrt{\frac{i g}{\Delta x}} \alpha(x) \xi_{1}(x, t)
\end{aligned}
$$

And $\frac{d \beta(x)}{d t}=\frac{d \alpha^{*}(x)}{d t}$ but with $\alpha^{*} \leftrightarrow \beta$ and new noises $\xi_{2}$.

- $\xi_{j}(x, t)$ are independent Gaussian noises of variance $1 / \Delta t$ for each $x, t, j$.
- Linear couplings $\omega_{x y}$ between $x$ and $y$ contain kinetics and external potential.

## Scattering Dynamics

- No seed wave for now.
- Coherent and incoherent evolution coupled together.
- Initially: GP ground state of trap.

Velocity distribution dynamics

velocities relative to COM moving at $\mathrm{v}_{\mathrm{Q}}$

FIRST-PRINCIPLES DYNAMICS TRACTABLE IN MANY CASES
e.g. four wave mixing:

- 150000 atoms.
-432x105×50 lattice.
That's over two million points.
- 1024 trajectories
- About a week on a single PC
- No truncation or linearization.

## Bosonic enhancement

 $\begin{array}{ll}\text { normal scattering } & \begin{array}{l}\text { bosonic enhancemen } \\ \text { "spontaneous emission" }\end{array} \\ \text { "stimulated emission" }\end{array}$

- Truncated Wigner is in error in such dilute regimes.
-This is due to the spurious virtual par ticles meant to mimic quantum noise.

## Correlation Dynamics

Correlations between scattered atoms at different velocities

$\qquad$ scatered atom having
$\mathrm{v}_{\mathrm{o}}-=9.8 \mathrm{mm/s}$ radial velocity
 Note: axial and tangential
correlations do not change Noie. axia and tangential
corralation so on to hane
apprecialiy on this timescale

- Further effects seen beyond previous truncated Wigner treatments [2]:
- Marked radial-only growth of phase grains with time.
- At short times $g^{(2)}\left(\mathrm{v}_{\mathrm{Q}},-\mathrm{v}_{\mathrm{Q}}\right) \gg 2$.
- Coherence $\left(g^{(1)}\right)$ and correlation $\left(g^{(2)}\right)$ lengths consistent with analytic estimates [3].

Four Wave Mixing

## Acknowledgments

We thank C. W. Gardiner, G. Shlyapnikov, J. Chwedeńczuk, M. Trippenbach, and P . Ziń for enlightening discussions.
